

ABSTRACT OF THE DISCLOSURE

5 An ophthalmic surgery system and method for treating presbyopia by
performing ablative photodecomposition of the corneal surface. The offset image of a
variable aperture, such as a variable width slit and variable diameter iris diaphragm, is
scanned in a preselected pattern to perform ablative sculpting of predetermined portions of a
corneal surface. The scanning is performed to ablate an optical zone sized to match the
10 patient pupil with a peripheral transition zone outside the pupil. The shape of the ablated
optical zone is different from the shape of the final optical correction on the anterior surface
of the cornea. The optical zone corrects for near-vision centrally and far-vision peripherally.
A movable image displacement mechanism enables radial displacement and angular rotation
of the profiled beam exiting from the variable aperture. The invention enables wide area
15 treatment with a laser having a narrower beam than the treatment area, and can be used in the
treatment of many conditions in conjunction with presbyopia such as hyperopia, hyperopic
astigmatism and irregular refractive aberrations.
